- Capacitive Sensors: Changes in fuel level alter the sensor's capacitance, which is measured via an RC circuit or specialized capacitance-to-digital converters.

- Ultrasonic Sensors: Measure distance from the sensor to the fuel surface by timing the ultrasonic pulse's echo.

- Signal Conditioning and Analog-to-Digital Conversion

- The analog signals from sensors are filtered and conditioned to minimize noise.

- The microcontroller's ADC (Analog-to-Digital Converter) converts the analog voltage into a digital value for processing.

- Data Processing and Calibration

- The microcontroller interprets the ADC readings, mapping them to corresponding fuel levels (e.g., 0-100%).

- Calibration algorithms compensate for sensor non-linearities and environmental factors.

- Display and Alert Logic

- The processed data is displayed graphically or numerically on the connected display.

- Thresholds are set for low fuel detection; upon crossing, visual or audible alerts are triggered.
