Question What are the primary functions of an operating system? The primary functions include managing hardware resources, providing a user interface, executing and managing applications, and ensuring security and file management. **Answer** What is process scheduling in an operating system? Process scheduling is the method by which the OS manages the execution of multiple processes by deciding which process runs at a given time, ensuring efficient CPU utilization. Explain the difference between preemptive and non-preemptive scheduling. Preemptive scheduling allows the OS to interrupt and suspend a currently running process to start or resume another, whereas non-preemptive scheduling lets processes run until they voluntarily release control. What is virtual memory, and why is it important? Virtual memory is a memory management technique that uses disk space to extend RAM, allowing processes to run larger than physical memory and providing isolation between processes. Define deadlock in the context of operating systems. A deadlock occurs when two or more processes are waiting indefinitely for resources held by each other, causing all involved processes to become blocked and unable to proceed. What are the differences between a monolithic kernel and a microkernel? A monolithic kernel includes all OS services in a single large kernel, whereas a microkernel provides minimal core functions with other services running in user space, improving modularity and security. What is the purpose of file system management in an OS? File system management organizes, stores, retrieves, and manages data on storage devices, providing a structured way for users and applications to access files efficiently and securely. Explain what inter-process communication (IPC) is. IPC refers to mechanisms that allow processes to communicate and synchronize with each other, sharing data or signals to coordinate their actions. What are common methods of process synchronization? Common methods include semaphores, mutexes, monitors, and condition variables, which help prevent race conditions and ensure correct process execution order. How does an operating system handle device management? The OS manages devices through device drivers, providing a standard

interface for hardware communication, controlling device access, and handling input/output operations efficiently.
